$p$-TH POWER TOTAL VARIATION REGULARIZATION
IN PHOTON-LIMITED IMAGING VIA ITERATIVE REWEIGHTING

Lasith Adhikari and Roummel F. Marcia

Department of Applied Mathematics, University of California, Merced, Merced, CA 95343 USA

ABSTRACT
Recent work in $\ell_p$-norm regularized sparsity recovery problems (where $0 \leq p < 1$) has shown that signals can be recovered with very high accuracy despite the fact that the solution to these nonconvex optimization problems are not necessarily the global minima but are instead potentially local minima. In particular, $\ell_p$-norm regularization has been used effectively for signal reconstruction from measurements corrupted by zero-mean additive Gaussian noise. This paper describes a $p$-th power total variation ($\text{TV}_p$) regularized optimization approach for image recovery problems in photon-limited settings using iterative reweighting. The proposed method iteratively convexifies a sequence of nonconvex TV subproblems using a weighted TV approach and is solved using a modification to the FISTA method for TV-based denoising. We explore the effectiveness of the proposed method through numerical experiments in image deblurring.

Index Terms— Total variation (TV), weighted TV, SPIRAL-TV$_p$, photon-limited imaging, Poisson noise

1. INTRODUCTION
In photon-limited imaging regimes, the number of photons received at the camera lens is relatively low. Such situations occur in nuclear medicine [1], night vision, and astronomy [2, 3]. Data in these applications are collected by counting discrete independent events and are accurately modeled using a Poisson noise model [4]:

$$y \sim \text{Poisson}(Af^*),$$

where $f^* \in \mathbb{R}^n$ is the true signal or image of interest, $A \in \mathbb{R}^{m \times n}$ is the linear projection matrix, and $y \in \mathbb{Z}_m^n$ is a vector of observed photon counts.

Under the Poisson model, an unknown signal $f^*$ is estimated by minimizing the negative Poisson log-likelihood function which is derived using the maximum likelihood principle. This inverse minimization problem is ill-posed if the dimension of the measurement $y$ is smaller than the dimension of the unknown signal $f^*$. Therefore, various penalization schemes are usually incorporated to pose the problem better.

When the signal to be reconstructed is known to be sparse in the canonical basis, it can be recovered accurately using a nonconvex $\ell_p$-norm regularization technique [5]. However, when the image is not sparse, a different regularization must be employed. The total variation (TV) seminorm penalty [6] has been commonly used as a sparsity measure and has been shown to be very effective as a regularization term for image reconstruction. More specifically, the TV seminorm measures the first-order difference between adjacent pixels in images. Thus, an image with a small TV seminorm means that it has homogeneous signal levels with few abrupt changes or edges. The recent work of Yan and Lu [7] generalizes this TV norm to the $p$-th power (TV$_p$), where $0 \leq p \leq 1$, by using a weighted TV minimization where the weights are computed to approximate the TV$_p$ regularized problem locally.

In this paper, we propose to regularize the negative Poisson log-likelihood function using the TV$_p$ penalization method in [7]. Specifically, we use the SPIRAL approach [8] to define a sequence of minimization subproblems with the TV$_p$ penalty. These subproblems are solved using the FISTA TV-based denoising method [9]. We explore the effectiveness of the proposed method through numerical experiments in image deblurring.

2. PROBLEM FORMULATION
2.1. Sparse Poisson Intensity Reconstruction
Under the inhomogeneous Poisson process model, the Poisson intensity reconstruction problem has the following constrained minimization form:

$$\begin{align*}
\text{minimize}_{f \in \mathbb{R}^n} & \quad \Phi(f) \equiv F(f) + \tau \text{pen}(f) \\
\text{subject to} & \quad f \succeq 0,
\end{align*}$$

where $\tau > 0$, $F(f)$ is the negative Poisson log-likelihood function

$$F(f) = 1^T Af - \sum_{i=1}^m y_i \log(e_i^T Af + \beta),$$

where $1$ is an $m$-vector of ones, $e_i$ is the $i$th canonical basis unit vector, $\beta > 0$ (typically $\beta \ll 1$) and pen : $\mathbb{R}^n \rightarrow \mathbb{R}$ is a penalty function (see e.g., [10]).
This minimization problem can be solved by minimizing a sequence of easier subproblems. In [8], \( F(f) \) is approximated by second-order Taylor series expansion, where the Hessian in the Taylor series is replaced by a scaled identity matrix \( \alpha_k I \), where \( \alpha_k > 0 \) (see e.g., [11, 12]). A simple manipulation to this quadratic approximation will lead into a sequence of subproblems of the form

\[
f^{k+1} = \arg \min_{f \in \mathbb{R}^n} \frac{1}{2} \| f - s^k \|_2^2 + \frac{\tau}{\alpha_k} \| f \|_{TV_k} \quad \text{subject to} \quad f \geq 0,
\]

where

\[
s^k = f^k - \frac{1}{\alpha_k} \nabla F(f^k)
\]

(see [8] for details).

### 2.2. Total Variation Regularization

The total variation seminorm is often used to promote sparsity in the gradient of an image, meaning the reconstructed image has very few abrupt changes in adjacent pixel intensities. The penalty function \( \text{pen}(f) \) in (2) can thus be replaced by \( \| f \|_{TV_k} \), and the subproblem can be rewritten of the form

\[
f^{k+1} = \arg \min_{f \in \mathbb{R}^m} \frac{1}{2} \| f - s^k \|_2^2 + \frac{\tau}{\alpha_k} \| f \|_{TV_k}
\]

subject to \( f \geq 0 \),

If \( f \in \mathbb{R}^{m \times n} \) is an \( m \times n \) image, the anisotropic TV seminorm of \( f \) is given by

\[
\| f \|_{TV_k} = \sum_{i=1}^{m-1} \sum_{j=1}^{n} |f_{i,j} - f_{i+1,j}| + \sum_{i=1}^{m-1} \sum_{j=1}^{n} |f_{i,j} - f_{i,j+1}|,
\]

while the isotropic TV seminorm of \( f \) is

\[
\| f \|_{TV_k} = \sum_{i=1}^{m-1} \sum_{j=1}^{n} \sqrt{(f_{i,j} - f_{i+1,j})^2 + (f_{i,j} - f_{i,j+1})^2} + \sum_{i=1}^{m-1} \sum_{j=1}^{n} |f_{i,n} - f_{i+1,n}| + \sum_{j=1}^{n-1} |f_{m,j} - f_{m+1,j}|.
\]

In [8], the TV-based nonnegative denoising subproblem (3) is solved using the fast gradient projection FISTA algorithm [9].

### 2.3. \( p \)-th Power Total Variation Regularization using Iterative Reweighting

We now propose to regularize the negative Poisson log likelihood function in (1) using a \( p \)-th power total variation [7], denoted by \( TV_p \) \((0 \leq p \leq 1)\). Then the sequence of subproblems has the following form

\[
f^{k+1} = \arg \min_{f \in \mathbb{R}^m} \frac{1}{2} \| f - s^k \|_2^2 + \frac{\tau}{\alpha_k} \| f \|_{TV_p}
\]

subject to \( f \geq 0 \),

where \( \| f \|_{TV_p} \) is defined as the anisotropic TV seminorm

\[
\| f \|_{TV_p} = \sum_{i=1}^{m-1} \sum_{j=1}^{n} |f_{i,j} - f_{i+1,j}|^p + \sum_{i=1}^{m-1} \sum_{j=1}^{n} |f_{i,j} - f_{i,j+1}|^p,
\]

or as the isotropic TV seminorm

\[
\| f \|_{TV_p} = \sum_{i=1}^{m-1} \sum_{j=1}^{n} \sqrt{(f_{i,j} - f_{i+1,j})^2 + (f_{i,j} - f_{i,j+1})^2} + \sum_{i=1}^{m-1} \sum_{j=1}^{n} |f_{i,n} - f_{i+1,n}|^p + \sum_{j=1}^{n-1} |f_{m,j} - f_{m+1,j}|^p.
\]

Note that when \( p < 1 \), both \( TV_p \) penalty functions are nonconvex, making the global minimum of (4) difficult to trace. In [7], the minimization of the nonconvex problem (4) is accomplished through the convexification of the nonconvex penalty function \( \| f \|_{TV_p} \) using a reweighting strategy. More specifically, a weighted TV seminorm is used to approximate the anisotropic TV seminorm

\[
\| f \|_{TV_p^w} = \sum_{i=1}^{m-1} \sum_{j=1}^{n} \alpha_{i,j} |f_{i,j} - f_{i+1,j}|^p + \sum_{i=1}^{m-1} \sum_{j=1}^{n} \beta_{i,j} |f_{i,j} - f_{i,j+1}|^p
\]

as well as the isotropic TV seminorm

\[
\| f \|_{TV_p^{w_i}} = \sum_{i=1}^{m-1} \sum_{j=1}^{n} \alpha_{i,j} (f_{i,j} - f_{i+1,j})^2 + \sum_{i=1}^{m-1} \sum_{j=1}^{n} \beta_{i,j} (f_{i,j} - f_{i,j+1})^2 + \sum_{i=1}^{m-1} \sum_{j=1}^{n} \alpha_{n,i} |f_{i,n} - f_{i+1,n}|^p + \sum_{j=1}^{n-1} \beta_{m,j} |f_{m,j} - f_{m+1,j}|^p.
\]

In the above weighted TV definitions, \( \alpha_{i,j} > 0 \) and \( \beta_{i,j} > 0 \) are coefficients whose values are computed using \( f \) in the previous iterate \( k \):

\[
\alpha_{i,j} = \left( \frac{|f_{i,j}^{(k)}|}{|f_{i+1,j}^{(k)}|} + \epsilon \right)^{p-1},
\]

\[
\beta_{i,j} = \left( \frac{|f_{i,j}^{(k)}|}{|f_{i,j+1}^{(k)}|} + \epsilon \right)^{p-1},
\]

where \( \epsilon > 0 \) to prevent the weights from being arbitrary large. By substituting (5) and (6) for \( \alpha_{i,j} \) and \( \beta_{i,j} \) respectively in the weighted TV definitions, it can be shown that \( \| f \|_{TV_p^w} \approx \| f^{(k)} \|_{TV_p^{w_i}} \) and \( \| f \|_{TV_p^{w_i}} \approx \| f^{(k)} \|_{TV_p^{w_i}} \) (see [7] for details).

### 2.4. Modified Dual Approach with Weighted TV Norms

Using the weighted TV functions as defined in the Section 2.3, we now show how to modify the FISTA approach of dual problem construction [9, 13]. In particular, we use the exact
Let $\mathcal{P}_A$ be the set of matrix-pairs $(p_1, q_1)$ where $p_1 \in \mathbb{R}^{(m-1) \times n}$ and $q_1 \in \mathbb{R}^{m \times (n-1)}$ satisfying

$$|p_{i,j}| \leq 1, \quad i = 1, \ldots, m - 1, \quad j = 1, \ldots, n,$$

$$|q_{i,j}| \leq 1, \quad i = 1, \ldots, m, \quad j = 1, \ldots, n - 1.$$  

Similarly, let $\mathcal{P}_T$ be the set of matrix-pairs $(p_2, q_2)$ where $p_2 \in \mathbb{R}^{(m-1) \times n}$ and $q_2 \in \mathbb{R}^{m \times (n-1)}$ that satisfy

$$p_{i,j}^2 + q_{i,j}^2 \leq 1, \quad i = 1, \ldots, m - 1, \quad j = 1, \ldots, n - 1,$$

$$|p_{i,n}| \leq 1, \quad i = 1, \ldots, m - 1,$$

$$|q_{m,j}| \leq 1, \quad j = 1, \ldots, n - 1.$$  

We redefine the linear operator $\mathcal{L} : \mathbb{R}^{(m-1) \times n \times \mathbb{R}^{m \times (n-1)}} \rightarrow \mathbb{R}^{m \times n}$ as follows:

$$\mathcal{L}(p_i, q_i)_{i,j} = \alpha_{i,j} p_{i,j} - \alpha_{i-1,j} p_{i-1,j} + \beta_{i,j} q_{i,j} - \beta_{i-1,j} q_{i-1,j} - 1,$$

where $\ell$ is 1 or 2, and we assume that $p_{i,0} = q_{0,j} = 0$ for $i = 1, \ldots, m$, $j = 1, \ldots, n$. The operator $\mathcal{L}^T : \mathbb{R}^{m \times n} \rightarrow \mathbb{R}^{(m-1) \times n \times \mathbb{R}^{m \times (n-1)}}$ is given by $\mathcal{L}^T(f) = (p_e, q_i)$, where $p_{i,j} = f_{i,j} - f_{i+1,j}$ and $q_{i,j} = f_{i+1,j} - f_{i,j+1}$. Since our subproblems (4) are non-negatively constrained, $P_C$ is the orthogonal projection operator on to the set $C = [0, \infty)$. 

Now note that the following two relations

$$\alpha |x| = \max_p \{ \alpha x : |p| \leq 1 \},$$

$$\sqrt{\alpha^2 x^2 + \beta^2 y^2} = \max_{p_1, p_2} \{ \alpha x p_1 + \beta y p_2 : p_1^2 + p_2^2 \leq 1 \},$$

hold true for weights $\alpha > 0$ and $\beta > 0$. Therefore, the anisotropic weighted TV seminorm can be written as the maximization problem

$$||f||_{TV_w} = \max_{(p_1, q_1) \in \mathcal{P}_A} T_1(f, p_1, q_1),$$

where

$$T_1(f, p_1, q_1) = \sum_{i=1}^{m-1} \sum_{j=1}^{n} \alpha_{i,j} (f_{i,j} - f_{i+1,j}) p_{i,j}$$

$$+ \sum_{i=1}^{m} \sum_{j=1}^{n-1} \beta_{i,j} (f_{i,j} - f_{i,j+1}) q_{i,j}.$$  

Similarly, the isotropic weighted TV seminorm also can be written as the maximization problem

$$||f||_{TV_w} = \max_{(p_2, q_2) \in \mathcal{P}_T} T_2(f, p_2, q_2),$$

where

$$T_2(f, p_2, q_2) = \sum_{i=1}^{m-1} \sum_{j=1}^{n} \alpha_{i,j} (f_{i,j} - f_{i+1,j}) p_{i,j}$$

$$+ \beta_{i,j} (f_{i,j} - f_{i,j+1}) q_{i,j}$$

$$+ \sum_{i=1}^{m} \sum_{j=1}^{n-1} \alpha_{i,n} (f_{i,n} - f_{i+1,n}) p_{i,n}$$

$$+ \sum_{j=1}^{n-1} \beta_{m,j} (f_{m,j} - f_{m,j+1}) q_{m,j}.$$  

With the above defined notations, we have

$$T_1(f, p_1, q_1) = \text{Tr}(\mathcal{L}^T(p_1, q_1)^T f),$$

$$T_2(f, p_2, q_2) = \text{Tr}(\mathcal{L}(p_2, q_2)^T f).$$

Hereafter we can follow the same procedure explained in [9] to obtain the dual problem with the weighted TV norm. This dual problem is iteratively solved using a fast gradient projection method (see [9] for more details).

### 3. Numerical Experiments

In this section, we demonstrate the effectiveness of the proposed algorithm, which we call SPiRAL-TV$_p$. In particular, we consider an image deblurring problem for which TV norm regularization is highly suitable.

In this experimental setup, we use the Shepp-Logan phantom image of size $128 \times 128$ available in the MATLAB’s image processing toolbox as the true image $f^*$ (see Fig. 1(a)). The true detector blurred image (see Fig. 1(b)) was obtained by $A f^*$, where $A$ is a blurring operator ($f^*$ is convolved with some blur matrix). Finally, a Poisson noisy observation matrix of size $128 \times 128$ is simulated by MATLAB’s `poissrnd` function. The Poisson noisy observation matrix is shown in Fig. 1(b), where the mean photon count is 45.8 with a maximum of 398.

![Image](image-url)  

**Fig. 1.** Experimental setup: (a) Shepp-Logan head phantom as true image, (b) blurred phantom image, (c) Poisson noisy phantom image with mean count 45.8.

We implemented the SPiRAL-TV$_p$ algorithm in MATLAB R2013a (on a PC with Intel Core i7 2.7GHz Processor with 8GB memory) by modifying existing codes of the SPIRAL method [14] and the TV-based FISTA denoising method.
In this paper, we have formulated a TV$_p$ regularized negative log-likelihood function for photon-limited imaging problems. This nonconvex TV$_p$ regularization problem is solved in a convex setting by using a reweighting strategy for each iteration. The SPIRAL-TV$_1$ solution is used as the warm initial point in the proposed SPIRAL-TV$_p$ method, and we proceed with this strategy by reducing the $p$-value. Under the warm-start strategy, the proposed SPIRAL-TV$_p$ algorithm will converge to a reasonably good local solution that is more accurate than the SPIRAL-TV$_1$ global solution. Since the anisotropic TV is related to the $\ell_1$-norm, the SPIRAL-TV$_p$ with the anisotropic TV leads to more accurate results than with the isotropic TV. In our experience with this particular data set, there is no any significant improvement in reconstructions for $p$-values less than 0.8. While the proposed SPIRAL-TV$_p$ method leads to more accurate results with less artifacts, it requires more computational effort than SPIRAL-TV$_1$ due to the iterative nature of the warm-start strategy.

5. DISCUSSION AND CONCLUSION

The results of the experiments described in the Section 3 for anisotropic and isotropic TV regularization are presented in Figs. 2 and 3 respectively. For the anisotropic TV regularization, the SPIRAL-TV$_{0.8}$ reconstruction has RMSE = 11.57% and PSNR = 30.95 dB while the reconstruction for SPIRAL-TV$_{1}$ reconstruction has RMSE = 11.90% and PSNR = 30.70 dB. For the isotropic TV regularization, the SPIRAL-TV$_{0.8}$ reconstruction has RMSE = 14.45% and PSNR = 29.02 dB while the reconstruction for SPIRAL-TV$_{1}$ reconstruction has RMSE = 14.80% and PSNR = 28.80 dB. In both cases and both metrics, the SPIRAL-TV$_{0.8}$ reconstructions show improvement over the SPIRAL-TV$_{1}$ reconstructions. Furthermore, the SPIRAL-TV$_{0.8}$ reconstructions recovered the actual gray area in the phantom body without losing the edge details and has less prominent cloud noise-like texture (see red zoomed areas in Fig. 2 (c) and (f) and Fig. 3 (c) and (f)).
