Abstract—An electrolarynx is a speaking aid device to artificially generate excitation sounds to help laryngectomees produce electrolaryngeal (EL) speech. Although EL speech is quite intelligible, its naturalness significantly suffers from the unnatural fundamental frequency ($F_0$) patterns of the mechanical excitation sounds. To make it possible to produce more naturally sounding EL speech, we have proposed a method to automatically control $F_0$ patterns of the excitation sounds generated from the electrolarynx based on the statistical $F_0$ prediction, which predicts $F_0$ patterns from the produced EL speech in real-time. In our previous work, we have developed a prototype system by implementing the proposed real-time prediction method in an actual, physical electrolarynx, and through the use of the prototype system, we have found that improvements of the naturalness of EL speech yielded by the prototype system tend to be lower than that yielded by the batch-type prediction. In this paper, we examine negative impacts caused by latency of the real-time prediction on the $F_0$ prediction accuracy, and to alleviate them, we also propose two methods, 1) modeling of segmented continuous $F_0$ (CF0) patterns and 2) prediction of forthcoming $F_0$ values. The experimental results demonstrate that 1) the conventional real-time prediction method needs a large delay to predict CF0 patterns and 2) the proposed methods have positive impacts on the real-time prediction.

I. INTRODUCTION

Production of electrolaryngeal (EL) speech is one of the major alternative speaking methods for laryngectomees. EL speech is produced using an electrolarynx, which is typically held against the neck to mechanically generate artificial excitation signals. The generated excitation signals are conducted into the speaker’s oral cavity, and are articulated to produce EL speech. EL speech is relatively intelligible but its naturalness is very low owing to unnatural fundamental frequency ($F_0$) patterns of the mechanically generated excitation signals.

To address this issue of EL speech, several methods have been proposed to control $F_0$ patterns of the excitation signals generated from an electrolarynx additionally using intention-ally controllable signals, such as expiratory air pressure [1], up and down switched controlled by a finger [2], and forearm movements [3]. Although these methods can change the $F_0$ patterns, it is inherently difficult to control these signals to generate natural $F_0$ patterns corresponding to linguistic content of the speech.

To generate more natural $F_0$ patterns, we have proposed a method to control $F_0$ values [4] based on statistical $F_0$ prediction [5] [6] [7]. In this framework, $F_0$ patterns are predicted not according to signals consciously provided by the speaker as in the other control methods but using only the produced EL speech signals as shown in Fig. 1. Statistical voice conversion techniques [8] [9] have been successfully applied to this prediction task. Relatively natural $F_0$ patterns can be predicted using statistics extracted in advance from parallel data consisting of utterance pairs of EL speech and natural speech. Our preliminary experimental results through a simulation have demonstrated that the proposed method yields significant improvements in naturalness while causing no degradation in listenability and intelligibility compared to the original EL speech [4][10].

In our previous work [11], we have developed a prototype system by implementing our proposed $F_0$ control method of an electrolarynx based on statistical $F_0$ prediction. We have confirmed that the naturalness of EL speech is significantly improved by the use of our prototype system. On the other hand, we have also found that improvements of the naturalness of EL speech yielded by the prototype system tend to be lower than that yielded by our conventional system based on batch-type prediction. It is possible that the real-time statistical $F_0$ prediction requires a large delay time to ensure sufficient $F_0$ prediction accuracy. Moreover, because the prototype system also needs additional processing delay, its large delay time significantly degrades naturalness of the enhanced EL speech in the form of causing larger mismatch between articulation behavior and the predicted $F_0$ patterns.

In this paper, we examine the effect of the delay time on the real-time statistical $F_0$ prediction. Moreover, to address the negative impacts caused by latency of the real-time prediction on the $F_0$ prediction accuracy, we propose two methods: 1) modeling of segmented continuous $F_0$ (CF0) patterns to shorten the required delay time in real-time statistical $F_0$ prediction and 2) prediction of forthcoming $F_0$ values to cancel the impact of the processing delay of the prototype system. Through the experimental evaluation, we demonstrate that 1) the delay time required to predict CF0 patterns in the conventional prediction method can be significantly reduced by using the segmented CF0 modeling strategy, and 2) the negative impacts of the processing delay can be effectively...
alleviated by predicting the forthcoming \( F_0 \) values.

II. DIRECT CONTROL OF ELECTROLARYNX BASED ON
STATISTICAL \( F_0 \) PREDICTION [4]

A. Strategy of Direct Control of Electrolarynx

Our proposed system (shown in Fig. 1) to directly control \( F_0 \) patterns of the excitatory signals generated from an electrolarynx consists of prediction and articulation processes. In the prediction process, the \( F_0 \) value is predicted from EL speech produced by a laryngectomee frame by frame using the real-time voice conversion algorithm. In the articulation process, the laryngectomee produces the EL speech by articulating the excitation sounds generated from the electrolarynx based on the predicted \( F_0 \) values. Therefore, this system allows laryngectomees to directly produce enhanced EL speech with more natural \( F_0 \) patterns corresponding to linguistic contents.

B. Statistical \( F_0 \) Prediction Method

We briefly review our statistical \( F_0 \) prediction method [5] [6] [7], which exploits the idea of statistical voice conversion techniques [8] [9]. The aim of this method is to predict \( F_0 \) contours from the spectral parameters of EL speech. We describe training, batch-type prediction, real-time prediction processes and problems of delay arising in real-time processing.

In the training process, a parameter set \( \lambda \) of the joint probability density function \( P((X_t^1, Y_t^1)^\top | \lambda) \) modeled by a Gaussian mixture model (GMM) is trained [12] using a parallel data set consisting of utterance pairs of the EL speech and target normal speech, where \( X_t \) and \( Y_t \) denote source features and target features at time frame \( t \), respectively, and \( \top \) denotes transposition. The corresponding joint vector features can be obtained by performing automatic frame alignment between the EL speech and the target normal speech with dynamic time warping. As the source features \( X_t \), the spectral segment features of EL speech are extracted on a frame-by-frame basis from the mel-cepstrum at multiple frames around the current frame \( t \) [13]. The target features \( Y_t = [y_t, \Delta y_t]^\top \) consist of the static and delta (time derivative) components of the log-scaled \( F_0 \) value \( y_t \), extracted on a frame-by-frame basis from the target normal speech. Note that to improve prediction accuracy, we use continuous \( F_0 \) (CF0) patterns which interpolate unvoiced frames of \( F_0 \) patterns by using spline interpolation, and remove micro-prosody [14].

In the batch-type prediction process, given the spectral segment sequence \( X = [X^1, \ldots, X^T]^\top \) of EL speech, the most likely \( F_0 \) sequence \( \{y_1, \ldots, y_T\}^\top \) can be obtained as follows:

\[
\hat{y}_t = \text{argmax}_y P(Y | X, \lambda) \quad \text{subject to} \quad Y = W y, \tag{1}
\]

\[
P(Y | X, \lambda) = \sum_m P(Y | X, \lambda, m) P(m | X, \lambda).
\]

\[
= P(Y | X, \tilde{m}) P(\tilde{m} | X, \lambda), \tag{2}
\]

\[
\tilde{m} = \text{argmax}_m P(m | X, \lambda), \tag{3}
\]

\[
P(Y | X, \tilde{m}) = \mathcal{N}(Y; E_m(Y|X), D_m(Y|X))
\]

\[
= \prod_{t=1}^T \mathcal{N}(Y_t; E_m(Y_t|X), D_m(Y_t|X)), \tag{4}
\]

where \( Y = [Y^1, \ldots, Y^T]^\top \) denotes the joint static and dynamic feature vector sequence, \( W \) is a linear transform to append dynamic feature vectors into the static feature sequence, \( m = \{m_1, \ldots, m_T\} \) indicates a sequence of mixture indices, \( E_m(Y|X) \) is the conditional mean vector at frame \( t \), which is given by the mixture-dependent linear transformation of the source feature vector \( X_t \), and \( D_m(Y|X) \) is the conditional covariance matrix depending on the mixture component \( m_t \). The ML estimate of \( F_0 \) sequence \( \hat{y} \) is analytically determined as follows:

\[
\hat{y}_t = (W^T D_m(Y|X)^{-1} W)^{-1} W^T D_m(Y|X)^{-1} E_m(Y|X). \tag{5}
\]

The real-time prediction process is achieved by using a computationally efficient real-time voice conversion method [15] based on a low-delay conversion algorithm [16]. To approximate the batch-type prediction process with the frame-wise prediction process, we divide the \( F_0 \) sequence \( y \) into overlapped (\( L + 1 \))-dimensional segment vectors \( \{y^l_t\} \) at individual frames. With treating the segment vectors as a latent variable, the following linear dynamical system can be designed [17]:

\[
y^{l+1}_t = J y^{l-1}_t + [0 L \ldots 0]^\top + n^{\Delta y}_t, \tag{6}
\]

\[
\tilde{y}^{\Delta y}_t = n^{\Delta y}_t, \tag{7}
\]

where the state transition matrix \( J \) just shifts the previous segment vector \( y^{l-1} \) and the linear transform \( w \) to calculate the dynamic features at frame \( t \) from the segment vector. The observation \( y^{\Delta y}_t \), a parameter \( \mu^{\Delta y}_t \) process noise \( n^{\Delta y}_t \), and observation noise \( n^{\Delta y}_t \) are described with the conditional mean vector \( \mu^{\Delta y}_t \) and covariance matrix \( D^{\Delta y}_t \) at frame \( t \). The segment vector is recursively updated frame by frame with Kalman filtering, and its first component \( y_{L-1} \) is used as the ML estimate \( y_{L-1} \). Therefore, the \( F_0 \) value at frame \( t \) is determined by considering all past frames, a current frame, and next \( L \) frames.

C. Effect of Delay Time on Real-time \( F_0 \) Prediction Accuracy

In the previous work [16], it has been reported in a spectral conversion task that the delay time depending on the segment feature length \( L \) in the real-time prediction process requires around 50 to 70 msec to maintain the conversion accuracy of the batch-type prediction process. On the other hand, no previous work has examined the effect of the delay time on the \( F_0 \) prediction accuracy. It is possible that longer delay will be required because \( F_0 \) is a suprasegmental feature, which has strong correlation over a wider range compared to segmental features, such as spectral parameters. This effect is expected to be stronger in CF0 patterns.

III. DEVELOPMENT OF PROTOTYPE SYSTEM

A. Implementation of Real-Time \( F_0 \) Control

A prototype system based on our proposed system was developed using a laptop and a digital/analog (D/A) converter shown in Table I. As shown in Fig. 1, EL speech produced from mouth of a laryngectomee is detected with a usual close-talk microphone. The EL speech signal is recorded on a laptop and \( F_0 \) patterns of normal speech are predicted on the fly by using the real-time statistical \( F_0 \) prediction. The predicted \( F_0 \) values are linearly converted to voltage values to control the \( F_0 \) values of the excitation signal generated by an electrolarynx. Then, an electric signal corresponding to the determined voltage values is generated with the D/A converter connected from the laptop to the electrolarynx. The
electrolarynx generates the excitation signal with the predicted 
F₀ values according to the input electric signal generated from 
the D/A converter.

As described in the previous section, the F₀ patterns are 
constantly delayed owing to latency of the real-time statistical 
F₀ prediction process. Moreover, additional latency is caused 
in the prototype system by the D/A converter. Figure 2 shows 
latency caused by each step. In our implementation, 50 msec 
latency is caused by the real-time statistical F₀ prediction. For 
the D/A part, it takes around 50 msec to write the digital signal 
on the D/A converter, where the digital signal to be written 
needs to be determined before starting writing. Consequently, 
the D/A part causes 100 msec latency. In total, 150 msec 
latency is caused in the prototype system.

B. Negative Impacts Caused by Latency

The F₀ patterns predicted by the prototype system strongly 
correlate to those by the simulated system [10], with a 
correlation coefficient higher than 0.9. This high correlation 
demonstrates that the proposed implementation is effective 
and the simulated system is able to effectively approximate 
the results of the prototype system. Through the use of 
the prototype system, we confirmed that it yields significant 
improvements in naturalness of EL speech while preserving its 
high intelligibility as expected in the previous evaluation [10]. 
However, we also found that the naturalness of enhanced EL 
speech tends to be lower than that yielded by the batch-type 
prediction. We assume that this degradation is caused by 1) 
the shorter delay time compared to the required delay time 
on the real-time prediction of C₀ patterns, and 2) additional 
processsing delay of the prototype system. It is necessary to 
compare the F₀ patterns predicted by the real-time prediction 
with those predicted by the batch-type prediction.

1Note that latency in the D/A part could be addressed by the development of a special device for the electrolarynx. Moreover, we have successfully implemented statistical VC processing on a digital signal processor (DSP) [18]. It is thus expected that all processors could be embedded into the electrolarynx and total latency will be decreased to the 50 msec caused by the real-time statistical F₀ prediction.

IV. PROPOSED METHODS FOR ADDRESSING LATENCY ISSUES

On our prototype system, the produced EL speech suffers 
from a misalignment between articulation and the constantly 
delayed F₀ patterns. To address this issue, we propose two 
methods for reducing the delay time caused by the real-time 
process while preserving F₀ prediction accuracy at the level 
of the batch-type prediction process.

A. Segmented Continuous F₀ Patterns

In the previous CF₀ modeling method, the prediction pro-
cess given in Eq. (1) is performed utterance by utterance. 
Because inter-frame correlation over an utterance is considered 
in this process, a long delay is required in real-time prediction 
to achieve sufficient prediction accuracy.

To reduce the delay time, we propose a segmented CF₀ 
pattern modeling method to make the range of which we 
consider inter-frame correlation shorter than an utterance. 
Shorter segments are first extracted from each utterance, and 
then, CF₀ patterns of individual segments (i.e., segmented 
CF₀ patterns) are modeled and predicted separately. In this 
paper, we determine the individual segments by extracting time 
frames of which the waveform power is over a pre-determined 
threshold. An example of the segmented CF₀ patterns is shown 
in Fig. 3. Note that the segmented CF₀ patterns are still 
different from the original F₀ pattern, which is segmented by 
unvoiced frames, in that 1) the segmented CF₀ patterns can 
also include unvoiced frames, and thus they tend to be longer 
than segments observed in the original F₀ patterns, and 2) 
each segmented CF₀ pattern varied more smoothly than the 
original F₀ patterns.

B. Forthcoming F₀ Prediction

In order to cancel the misalignment between articulation and 
the constantly delayed F₀ patterns predicted in the real-
time process, we investigate the possibility of predicting 
forthcoming F₀ values. We train the GMM for modeling the 
joint probability density P([Xₜ], [Yₜ+ℱ] | [A]) of the source 
features at frame t, [Xₜ], and the target features at frame t + F, 
[Yₜ+ℱ]. The trained GMM is used to predict the F₀ value at F 
frames ahead. For example, if the latency of the prototype 
system is set to 200 msec, the trained GMM to predict the 
F₀ values at 200 msec ahead. Consequently, there is no 
mismatch between articulation and the predicted F₀ patterns.
It is expected that there is a tradeoff between the prediction accuracy and the setting of $F$; i.e., larger $F$ accepts a longer delay time in the real-time prediction process, which makes the real-time prediction accuracy close to the batch-type prediction accuracy; on the other hand, it is obviously more difficult to predict $F_0$ values at frames far away from the current one than those at closer frames.

V. EXPERIMENTAL EVALUATION

A. Experimental Conditions

We conducted four types of objective evaluation to examine the performance of the developed prototype system and the effectiveness of the proposed methods. The first evaluation is a comparison of the prediction accuracy among three types of $F_0$ pattern modeling, $F_0$, $CF_0$, and the proposed segmental $CF_0$ (Seg $CF_0$), in the batch-type prediction process. The second evaluation is a comparison of the accuracy of batch-type $F_0$ prediction and real-time $F_0$ prediction. The third evaluation is conducted to examine the effectiveness of the proposed segmental $CF_0$ modeling method in the real-time prediction process. The last evaluation is conducted to examine the effectiveness of the proposed forthcoming $F_0$ prediction method. The source speech was EL speech uttered by a male speaker, and the target speech was normal speech uttered by a professional female speaker. Each speaker uttered about 50 sentences in the ATR phonetically balanced sentence set [19]. We conducted a 5-fold cross validation test in which 40 utterance pairs were used for training, and the remaining 10 utterance pairs were used for evaluation. Sampling frequency was set to 16 kHz.

We employed FFT analysis with a 25 msec hanning window to extract the mel-cepstra of EL speech as the spectral parameters. The frame shift length was set to 5 msec. As the source features, the spectral segment features were extracted from the mel-cepstra at the current ±4 frames. On the other hand, $F_0$ values of normal speech were extracted with STRAIGHT $F_0$ analysis [20] and $CF_0$ patterns were generated as the target feature using a low-pass filter with 10 Hz cut-off frequency. Moreover, the target $F_0$ patterns were shifted so that their mean value was equal to 100 Hz to predict $F_0$ patterns suitable for the source male speaker.

B. Comparison of $F_0$ Modeling Methods in Batch-type $F_0$ Prediction

We evaluated the prediction accuracy of each $F_0$ pattern modeling method in the batch-type process using the correlation coefficient between the predicted $F_0$ pattern and the target $F_0$ pattern. The number of mixture components of the GMM was optimized separately in each modeling method.

Table II shows the results as well as the number of mixture components optimized for each modeling method. $CF_0$ yields a significant improvement in the prediction accuracy compared to the original $F_0$ as reported in [7]. The proposed segmented $CF_0$ modeling method (Seg $CF_0$) preserves such an improvement relatively well while minimizing degradation of the prediction accuracy.

C. Comparison of the Accuracy of Batch-type $F_0$ Prediction and Real-time $F_0$ Prediction

As mentioned in Section IV-A, it is possible in the real-time prediction that the larger delay time is required in the $CF_0$ pattern than in the $F_0$ pattern to achieve the prediction accuracy comparable to that of the batch-type prediction. To examine this possibility, we calculated a correlation coefficient between the $F_0$ pattern predicted by the real-time prediction with various settings of the delay time and that by the batch-type prediction.

The result of a comparison between the $CF_0$ and $F_0$ patterns is shown in Fig. 4. As for the $F_0$ pattern, even if setting the delay time to 60 msec (corresponding to $L = 5$), a quite high correlation coefficient (around 0.89) is achieved. On the other hand, as for the $CF_0$ pattern, the predicted patterns are quite different from those by the batch-type process, showing that the correlation coefficient is less than 0.8 when setting the delay time to less than 85 msec. Moreover, its accuracy convergence is much slower compared to that observed in the $F_0$ pattern. Consequently, in the $CF_0$ pattern, the delay time needs to be set to around 250 msec to achieve the prediction accuracy comparable to that of the batch-type prediction.

D. Evaluation of the Proposed Segmental $CF_0$ Modeling

We evaluated the real-time prediction accuracy of each $F_0$ modeling method using the correlation coefficient between the predicted $F_0$ pattern and the target $F_0$ pattern. To evaluate only

<table>

</tbody>
</table>

![Fig. 4. Comparison of the accuracy of batch-type $F_0$ prediction and real-time $F_0$ prediction.](image1)

![Fig. 5. Relationship of the delay time and each $F_0$ pattern on real-time $F_0$ prediction accuracy (w/ delay time correction at the time of evaluation).](image2)
the prediction accuracy, the effect of the misalignment between the predicted and the target \( F_0 \) patterns, which is observed on the prototype system, was removed in this evaluation by shifting the predicted \( F_0 \) patterns according to the delay time settings in calculation of the correlation coefficient.

The results are shown in Fig. 5. As for the \( F_0 \) pattern, although the prediction accuracy quickly converges at around 60 msec of the delay time, the resulting correlation coefficient is lower than 0.4 because the prediction accuracy of the batch-type prediction is also low, as shown in Table II. As for the \( CF_0 \) pattern, the converged prediction accuracy is significantly higher than that in the \( F_0 \) pattern, as also observed in Table II, and its convergence is very slow. To achieve sufficient prediction accuracy, the delay time needs to be set to around 250 msec, as also observed in Fig. 4. On the other hand, the use of the proposed segmented \( CF_0 \) patterns makes the convergence faster than that of the \( CF_0 \) patterns while preserving its prediction accuracy. Consequently, the prediction accuracy comparable to the batch-type prediction can be achieved by setting the delay time to around 150 msec.

E. Evaluation of the Proposed Forthcoming \( F_0 \) Prediction

We evaluated the real-time prediction accuracy also considering the effect of the misalignment between articulation and the delayed \( F_0 \) patterns predicted in the real-time process, which was observed in a practical situation, using the correlation coefficient between the predicted \( F_0 \) pattern without any correction of the delay time and the target \( F_0 \) pattern.

The proposed forthcoming \( F_0 \) prediction method was applied to the \( CF_0 \) pattern and its effectiveness was examined. The result is shown in Fig. 6. If not using the proposed forthcoming \( F_0 \) prediction, the delay time is set to longer, the prediction accuracy gets lower. This result shows that the adverse effect of the misalignment on the actual prediction accuracy is significantly large. This issue is well addressed by using the proposed forthcoming \( F_0 \) prediction. Consequently, by setting the delay time to around 250 msec, the real-time prediction with the proposed forthcoming \( F_0 \) prediction method makes it possible to achieve prediction accuracy comparable to that of the batch-type prediction.

VI. CONCLUSION

In this paper, we have examined negative impacts caused by latency of the real-time prediction on \( F_0 \) prediction accuracy, and to alleviate them, we have also proposed two methods, 1) modeling of segmented continuous \( F_0 \) (\( CF_0 \)) patterns and 2) prediction of forthcoming \( F_0 \) values. The experimental results have demonstrated that 1) the conventional real-time prediction needs a large delay to predict \( CF_0 \) patterns and 2) the proposed methods have positive impacts on the real-time prediction.
