ABSTRACT

This paper presents two different approaches to derive the asymptotic distributions of the robust Adaptive Normalized Matched Filter (ANMF) under both $H_0$ and $H_1$ hypotheses. More precisely, the ANMF has originally been derived under the assumption of partially homogenous Gaussian noise, i.e. where the variance is different between the observation under test and the set of secondary data. We propose in this work to relax the Gaussian hypothesis: we analyze the ANMF built with robust estimators, namely the M-estimators and the Tyler’s estimator, under the Complex Elliptically Symmetric (CES) distributions framework. In this context, we derive two asymptotic distributions for this robust ANMF. Firstly, we combine the asymptotic properties of the robust estimators and the Gaussian-based distribution of the ANMF at finite distance. Secondly, we directly derive the asymptotic distribution of the robust ANMF.

Index Terms— Adaptive Normalized Match Filter, M-estimators, Tyler’s estimator, Complex Elliptically Symmetric distributions, non-Gaussian detection, robust estimation theory.

1. INTRODUCTION

In the general statistical signal processing area, the detection problem is an important topic of research. For instance, one can cite the works in radar processing [1–4]. Since in practice, the noise parameters are unknown, an estimation step is required leading to the so-called adaptive detection processes. Among these unknown parameters, the noise Covariance Matrix (CM) is probably one of the most important since the resulting performance of adaptive detectors mainly relies on the estimation accuracy of this CM. This is the case for the Adaptive Matched Filter (AMF) [5], the Kelly’s test [6] and the Adaptive Normalized Match Filter (ANMF) [1]. Generally, the CM is estimated thanks to the so-called Sample Covariance Matrix (SCM). Although this estimator is very simple and provides optimal performance under a Gaussian noise, the resulting adaptive detector performance can strongly be degraded when the noise turned to be non-Gaussian, heterogeneous or when it contains outliers/jammers.

To fill these gaps, a general framework on robust estimation theory has been extensively studied in the statistical community in the 1970s following the seminal works of Huber and Maronna [7,8]. The multivariate real case has been recently extended to the complex case [9–11], more adapted for signal processing applications. Under this robust theory framework, most of recent works in CM estimation considers the broader class of Complex Elliptically Symmetric (CES) distributions. A complete review on CES applied to array processing can be found in [9].

In this CES framework, the so-called M-estimators [8] and the Tyler’s estimator [11, 12] present alternatives to the Gaussian-based SCM. Although these robust estimators provide good results in practice [10], the statistical analysis of the resulting adaptive detectors is a difficult point. This is mainly due to the non explicit form of these estimators, defined through fixed point equations. However, their asymptotic properties have been recently derived in [9, 10]. Following these works, the aim of this paper is to derive the asymptotic properties of the ANMF built with these estimators, namely the M-estimators and the Tyler’s estimator, under both $H_0$ (absence of target) and $H_1$ (presence of target) hypotheses. The interest of such an analysis is to provide a better statistical characterization of the ANMF than the one based on the NMF [13].

The paper is organized as follows: next section provides the general background of this work as well as a recall on the main results concerning the statistics of the NMF and ANMF detection tests under both Gaussian assumption and CES distributions background. Section III gives without proof, the results presented in [14] concerning the asymptotic distribution of the ANMF built with robust estimators. Then, Section IV presents two different ways to derive the statistic of the ANMF built with any M-estimators for both $H_0$ and $H_1$ hypotheses. Finally, some conclusions and perspectives are drawn in the last section.

The following convention is adopted: italic indicates a scalar quantity, lower (resp. upper) case boldface indicates a vector (resp. matrix) quantity and upper case boldface a matrix. $^T$ and $^H$ represent respectively the transpose and the transpose conjugate operators, Tr(\cdot) denotes the trace operator, $\mathbb{1}_{\{0,1\}}(\cdot)$ is the $[0,1]$-indicator function, vec the vec operator and $\mathcal{CN}(\mu,\Sigma)$ stands for the complex (resp. real) Gaussian distribution while $\mathcal{CES}$ stands for the Complex Elliptically Symmetric distribution.

2. BACKGROUND

2.1. The Normalized Matched Filter (NMF)

Detecting a complex signal corrupted by an additive Gaussian noise $x \sim \mathcal{CN}(0,\sigma^2 \mathbf{I})$ in a $m$-dimensional complex observation vector $y$ can be stated as the following binary hypothesis test:

$$\begin{align*}
H_0 : \ y = c_{i} & \quad i = 1, \ldots, N \\
H_1 : \ y = \alpha \ p + c_{i} & \quad i = 1, \ldots, N ,
\end{align*}$$

(1)

where $p$ is a perfectly known complex steering vector, $\alpha$ is the unknown signal amplitude and where the $c_{i} \sim \mathcal{CN}(0, \mathbf{M})$ are $N$ signal-free independent measurements, traditionally called the secondary data, used to estimate the background CM $\mathbf{M}$. When the $\mathbf{M}$
$M$ is known and the variance $\sigma^2$ is unknown, this binary hypothesis test is solved by the Generalized Likelihood Ratio Test (GLRT) theory leading to a well-known Normalized Matched Filter [13] denoted $H(\cdot)$ and defined on $[0,1]$ by

$$H(M) = \frac{|\mathbf{p}^H \mathbf{M}^{-1} \mathbf{y}|^2}{|\mathbf{p}^H (\mathbf{M}^{-1} - \mathbf{p}) |^2 |\mathbf{y}^H \mathbf{M}^{-1} \mathbf{y}|}.$$  

(2)

In order to derive the probability density function (PDF) of $H(M)$ under $H_1$ and $H_0$ hypothesis, let us set the signal-to-noise ratio (SNR) equal to $\delta = \alpha^2 \mathbf{p}^H \mathbf{M}^{-1} \mathbf{p} / \sigma^2$. It can be shown in [4] that $H(M)$, derived for heterogeneous Gaussian distribution, can be rewritten as $F(\alpha) = \frac{\mathbf{F}(\alpha)}{\mathbf{F}(2)}$ where $\alpha_1 = 1$, $\alpha_2 = m - 1$ and where $\alpha$ is the noncentrality parameter. The PDF of $F$ is given by:

$$p_F(u) = (m - 1) e^{-\delta} (1 + u)^{-m-1} F_1 \left( m, 1; \frac{u \delta}{u + 1} \right),$$

(3)

where $F_1(\alpha, \alpha_2; \cdot)$ is the complex confluent hypergeometric function. After a simple change of variable, the distribution of $H(M)$ takes the following form:

$$p_{H(M)}(u) = e^{-\delta} \beta_{1,m-1}(u) F_1 \left( m, 1; u \delta \right),$$

(4)

where $\beta_{1,m-1}(u) = (m - 1)(1 - u)^{m-2} \beta_0,1(1/u) (u)$ is the PDF of $\beta$-distribution with degrees of freedom $1$ and $m - 1$, denoted $\beta(1, m - 1)$. Thus, setting $\delta$ to zero simply leads to the $\beta(1, m - 1)$ PDF for $H(M)$ under $H_0$ hypothesis. Hence, the theoretical relationship between the detection threshold $\lambda$ and the Probability of False Alarm (PFA) is defined as:

$$P_{fa} = \mathbb{P}(H(M) > \lambda | H_0) = (1 - \lambda)^{m-1}.$$  

(5)

This relation will serve as a benchmark since it characterizes the case of a perfectly known covariance matrix for the detection test. When $\delta \neq 0$, the Probability of Detection $P_d$ for a given SNR $\delta$ and for a fixed value of the detection threshold $\lambda$ is given by:

$$P_d = \mathbb{P}(H(M) > \lambda | H_1)$$

$$= 1 - e^{-\delta} \int_0^\lambda \beta_{1,m-1}(u) F_1 \left( m, 1; u \delta \right) du.$$  

(6)

Note that, for efficient numerical computation of the previous equation (for any non-zero noncentrality parameter of the confluent hypergeometric function), it is better to use the following relationship:

$$F_1 \left( a, b; z \right) = e^z F_1 \left( b-a, z \right),$$

(7)

leading to

$$P_d = 1 - \int_0^\lambda \beta_{1,m-1}(u) e^{\delta (u-1)} F_1 \left( 1 - m, 1; -u \delta \right) du.$$  

(8)

2.2. The Adaptive Normalized Matched Filter (ANMF)

When an estimate $\hat{M}$ of the CM $M$ is plugged into the NMF (two-step GLRT), this results in the so-called ANMF or ACE (Adaptive Coherence Estimator) [1, 3]. Assuming that the SCM, defined as

$$\hat{M}_{SCM} = \frac{1}{N} \sum_{k=1}^N e_k e_k^H$$

is used, Kraut et al. have shown in [4] that $H(\hat{M}_{SCM})$ has the same distribution as $\frac{F}{F + 1}$ where $F \sim \frac{C_{\chi}^2(\delta)}{C_{\chi}^2(N-m+1)(0) 1 - b}$ and where $b \sim \beta(N-m+2, m-1)$. After simple but fastidious derivations, one obtains:

$$f_{H(\hat{M}_{SCM})}(x) = e^{-\frac{1}{K}} \int_0^1 u^{N-m+1} \left( 1 - u \right)^{m-1} (1 - x)^{N-m}$$

$$\times F_1 \left( N - m + 2, 1; \frac{\delta (1-u)}{1-xu} \right) du ,$$

(9)

where $K = \frac{\Gamma(N-m+1) \Gamma(m-1)}{\Gamma(N+1)}$. By setting $\delta = 0$ in the previous equation, the resulting PDF $f_{H(\hat{M}_{SCM})}$ of $H(\hat{M}_{SCM})$ under $H_0$ hypothesis can be retrieved [15]:

$$f_{H(\hat{M}_{SCM})}(x) = \frac{(N-m+1)(m-1)}{N+1} (1-x)^{N-m}$$

$$\times F_1 \left( N - m + 2, N - m + 2; N + 2, x \right),$$

(10)

where $F_1(\cdot, \cdot)$ is the hypergeometric function [16]. The theoretical relationship between the detection threshold $\lambda$ and the Probability of False Alarm $P_{fa}$ is defined as:

$$P_{fa} = \mathbb{P}(H(\hat{M}_{SCM}) > \lambda | H_0)$$

$$= (1 - \lambda)^{N-m+1} F_1 \left( N - m + 2, N - m + 2; N + 1; \lambda \right),$$

(11)

whereas the corresponding relationship between $P_d$ and the SNR $\delta$ for a fixed $P_{fa}$ leads to:

$$P_d = \mathbb{P}(H(\hat{M}_{SCM}) > \lambda | H_1)$$

$$= 1 - e^{-\delta} \int_0^\lambda du \frac{u^{N-m+1} (1-u)^{m-1} (1-x)^{N-m}}{(1-xu)^{N-m+2}}$$

$$\times F_1 \left( N - m + 2, 1; \frac{\delta (1-u)}{1-xu} \right) dx.$$  

(12)

2.3. M-estimators, Tyler’s estimator and asymptotic properties

This section presents the $M$-estimators, the Tyler’s estimator as well as their asymptotic properties. Details of the following results can be found in [9, 10] for $M$-estimators and in [11, 12, 17] for the Tyler’s estimator.

In the literature of radar detection and estimation, Spherically Invariant Random Vector (SIRV) modeling and Complex Elliptical Symmetric distributions (CES), originally introduced by Kelker in [18], have been considered and have been studied for their good statistical properties and for their good fitting to experimental non-Gaussian radar data [19]. They provide a multivariate location-scale family of distributions that primarily serve as long tailed alternatives to the multivariate Gaussian model. A good review of these distributions can be found in [9, 20]. Let $e$ be a $m$-dimensional complex random vector. $e$ follows a CES distribution if its PDF can be written as

$$g_e(e) = |e|^{-1} h_e \left( e, \mu \right),$$

(13)

where $h_e : \mathbb{R}^+ \rightarrow (\mathbb{C})$ is any function such that (13) defines a PDF, $\mu$ is the statistical mean and $\Sigma$ is a scatter matrix. It will be denoted $e \sim CES(\mu, \Sigma)$. $\Sigma$ reflects the structure of the CM of $e$, i.e. the covariance matrix is equal to $\Sigma$ up to a scale factor. One can notice that the Gaussian distribution is a particular case of CES. In this paper, we will assume that $\mu = 0$ and without loss of generality, the scatter matrix will be taken equal to the CM $M$. 

525
Now, let \((c_1, \ldots, c_N)\) be a \(N\)-sample of \(m\)-dimensional complex independent vectors with \(c_k \sim \mathcal{CN}(0, M)\), \(k = 1, \ldots, N\). The \(M\)-estimators are defined as the unique solution of the following equation
\[
\hat{M} = \frac{1}{N} \sum_{k=1}^{N} u(c_k^H \hat{M}^{-1} c_k) c_k c_k^H,
\]
where \(u(.)\) stands for any real-valued function that satisfies a set of general assumptions (see [9, 10]), mainly for ensuring the existence, uniqueness and convergence of the previous equation. Note that MLEs are particular solutions of the previous equation.

An attractive and powerful estimator, independent of the CES distribution, is the Tyler’s estimator also called the Fixed Point and defined as the solution of
\[
\hat{M} = \frac{1}{N} \sum_{k=1}^{N} c_k c_k^H \hat{M}^{-1} c_k.
\]

For all \(M\)-estimator \(\hat{M}\) which verifies equation (14), one has the important asymptotical statistical behavior:
\[
\sqrt{N} \left( \text{vec}(\hat{M} - M) \right) \xrightarrow{d} \mathcal{GCN} \left( 0, \nu_1, \nu_2, \Sigma_M, \Omega_M \right),
\]
where \(\hat{M}\) is the consistent limit of \(\hat{M}\) and \(\mathcal{GCN} \left( 0, \nu_1, \nu_2, \Sigma_M, \Omega_M \right)\) denotes the Generalized Complex Normal distribution with \(\Sigma_M\) the covariance matrix and \(\Omega_M\) the pseudo-covariance matrix defined as
\[
\Sigma_M = \nu_1 M^T \otimes \Sigma + \nu_2 \text{vec}(M) \text{vec}(M)^H, \\
\Omega_M = \nu_1 (M^T \otimes K) + \nu_2 \text{vec}(M) \text{vec}(M)^T,
\]
where \(K\) is the commutation matrix which transforms vec(A) into vec(A^T), \(\nu_1\) and \(\nu_2\) are real scalars relying on the CES distribution and given in [9, 21].

It is important to notice that the previous result is also valid for the SCM when the observations are Gaussian \((\nu_1 = 1\) and \(\nu_2 = 0\), see e.g. [22]) and for the Tyler’s estimator for CES-distributed observations \((\nu_1 = (m+1)/m\) and \(\nu_2 = -(m+1)/m^2\), see e.g. [17]). This shows that the asymptotic behavior of all these estimators is similar. More precisely, the \(M\)-estimators and the Tyler’s estimator behaves asymptotically the same as the SCM, it differs only from the scalar quantities \(\nu_1\) and \(\nu_2\).

### 2.4. Asymptotic properties of the ANMF built with M-estimates

The asymptotic behavior of all the presented estimators can then be extended to the ANMF thanks to the following result.

Let \(H(.)\) be a \(r\)-dimensional multivariate function on the set of \(m \times m\) positive-definite symmetric matrices with continuous first partial derivatives and such that \(H(M) = H(\lambda M)\) for all \(\lambda > 0\), i.e. \(H(.)\) is homogeneous of degree 0. For all \(M\) that verifies equation (16), one has the following result, derived in [9, 21]:
\[
\sqrt{N} \left( \text{vec}(H(M)) - H(M) \right) \xrightarrow{d} \mathcal{GCN} \left( 0, \lambda \Sigma_H, \Omega_H \right),
\]
where \(\Sigma_H\) and \(\Omega_H\) are defined as
\[
\Sigma_H = \nu_1 H'(M) (M^T \otimes M) H'(M)^H, \\
\Omega_H = \nu_1 H'(M) (M^T \otimes K) H'(M)^T,
\]
and \(H'(M) = \frac{\partial H(M)}{\partial \text{vec}(M)} = (h'_{ij})\) with \(h'_{ij} = \frac{\partial h_{ij}}{\partial m_{ij}}\) and \(m_{ij}\)’s denote the elements of vec(M), for \(j = 1, \ldots, m^2\).

When comparing to the asymptotic behavior of any function \(H\) with SCM argument \(M\), one obtains \(\nu_1 = 1\). For any function \(H\) with Tyler’s argument \(M\), we obtain \(\nu_1 = (m+1)/m\). This explains that any function \(H\) of \(M\)-estimators has the same asymptotic distribution than those of a Wishart matrix (SCM) with \(N/\nu_1\) degrees of freedom. It could also be interpreted as follows: under Gaussian assumption, \(M\)-estimators require \(\nu_1 N\) secondary data to reach the same performance as the SCM.

### 3. ASYMPTOTIC BEHAVIOR OF THE ANMF TEST

The goal of this section is to propose two different ways of deriving an approximate distribution of the test \(H(\hat{M})\) built with any \(M\)-estimators under both \(H_0\) and \(H_1\) hypotheses. The first approach consists in using the asymptotic distribution presented in section 2.4 for the different estimators while the second approach is to compute analytically the parameters \(\Sigma_H\), \(\Omega_H\) characterizing the asymptotic distribution of the ANMF given by equation (18).

#### 3.1. Correction of the degrees of freedom, compared to the Gaussian-based SCM

Let us first consider the two ANMF PDF given by (9) under \(H_1\) hypothesis and (10) under \(H_0\) hypothesis. Note that these two equations provide the exact distributions of \(H(\hat{M}_{SCM})\) under both \(H_0\) and \(H_1\) hypotheses when the observations \(y_1, y_2, \ldots, y_N\) are Gaussian distributed. Now, for \(N\) sufficiently large, equation (16) states that a \(M\)-estimator built with \(N\) \(\nu_1\) observations behaves as the SCM built with \(N\) observations. Consequently, combining this result with equations (9) and (10) or equivalently with equations (11) and (12), leads to the approximate distribution for \(H(\hat{M})\) under both hypotheses where \(\hat{M}\) stands for any \(M\)-estimator or for the Tyler’s estimator. The final theoretical relationship between the detection threshold \(\lambda\) and \(P_f\) is given by \(P_f = \mathbb{P}(H(\hat{M}) > \lambda | H_0)\) and the theoretical relationship between \(\lambda\) and \(P_d\) is given by \(P_d = \mathbb{P}(H(\hat{M}) > \lambda | H_1)\) therefore given by
\[
P_f = \frac{1}{\nu_0} \left( 1 - \lambda \right)^{\nu_0 - 1} \text{B}(\nu_0 - 1; a, b - 1; 1),
\]
and
\[
P_d = 1 - \frac{e^{-1}}{K} \int_0^1 du \int_0^\lambda u^{\nu_0 - 1} \frac{(1-u)^{m-1} (1-x)^{\nu_0 - 2}}{(1-u)x} dx,
\]
where \(K = \frac{\Gamma(a-1) \Gamma(m-1)}{\Gamma(b-1)}\), \(a = N/\nu_1 - m + 2\) and \(b = N/\nu_1 + 2\).

As illustrated in the simulations and although no rigorous proof is given, the previous result provides a very accurate PDF for \(H(\hat{M})\) even for small \(N\).

#### 3.2. Asymptotic covariance of the ANMF

Let us now turn to the asymptotic distribution of the ANMF for any CM estimator.

**Proposition 3.1** Let us consider the ANMF test defined by
\[
H(\hat{M}) = \frac{\text{vec}^H(\hat{M}^{-1}) y^2}{\text{vec}^H(\hat{M}^{-1}) \text{vec}(\hat{M}^{-1}) y^2}.
\]
This function \(H(.)\) is homogeneous of degree 0 and one can apply result given in (18). For any estimator \(\hat{M}\) satisfying equation
\[ \text{relationship:} \]

where \( \lambda \) and \( \mu \) are independent Gaussian random variables with zero mean and unit variance, respectively. The asymptotic variance \( \Sigma_{\text{asy}}(H) \) and pseudo-covariance \( \Omega_{\text{asy}}(H) \) of the ANMF statistic are given by

\[ \Sigma_{\text{asy}} = \Omega_{\text{asy}} = 2\mu \frac{H(M)}{N(H(M) - 1)^2}. \]  

\[ \text{Proof 3.1} \] The proof has been recently derived in [14] and is omitted here.

Notice that, contrary to the first approach, the previous asymptotic distribution is a distribution conditional to the observation \( y \) that appears in \( H(M) \). Consequently, a supplementary step is required to obtain the asymptotic distribution of \( H(M) \).

Let us rewrite the result of Proposition 3.1 as

\[ H(M) \sim N \left( \frac{2\mu H(M)}{N(H(M) - 1)^2} \right). \]  

4. EVALUATION OF PERFORMANCES

4.1. Evaluation of asymptotic performances under \( H_0 \)

According to result given by (24), for \( N \) large enough, considering that \( H(M) \sim N(X, \sigma^2_X) \) where \( \sigma^2_X = \frac{2\mu}{N} X(X - 1)^2 \) and \( X = H(M) \sim \beta(1, m - 1) \), one can obtain the asymptotic distribution \( f_{H(M)}(x) \) as follows

\[ f_{H(M)}(x) = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi} \sqrt{\lambda}} \exp \left( -\frac{1}{2} \left( \frac{x - \lambda}{\sqrt{\lambda}} \right)^2 \right) \beta_1(1, m - 1) dx. \]  

Now, if we denote \( \Phi(\cdot) \) the cumulative distribution of the Normal distribution, one obtains the corresponding asymptotic \( P_{fa} \) as follows

\[ P_{fa} = 1 - \int_{0}^{\infty} \beta_1(1, m - 1) \Phi \left( \frac{\sqrt{\lambda}}{\sqrt{2\mu}(x - 1)^2} \right) dx. \]  

4.2. Evaluation of asymptotic performances under \( H_1 \)

Here, we assume that the noise in the cell under test is Gaussian distributed whereas the secondary data are CES distributed. In that case, due to the fact that the \( M \)-estimator is independent of the CES distribution, the distribution of \( H(M) \) under \( H_1 \) hypothesis is given by \( P_{H(M)} \) (Equation (4)). According to the result given by (24), for \( N \) large enough, considering that \( H(M) \sim N(X, \sigma^2_X) \) where \( \sigma^2_X = \frac{2\mu}{N} X(X - 1)^2 \) and \( X = H(M) \sim \beta_1(1, m - 1) \), one can obtain the asymptotic distribution \( f_{H(M)}(x) \) as follows

\[ f_{H(M)}(x) = \int_{-\infty}^{\infty} \frac{1}{\sqrt{2\pi} \sqrt{\lambda}} \exp \left( -\frac{1}{2} \left( \frac{x - \lambda}{\sqrt{\lambda}} \right)^2 \right) p_{H(M)}(x) dx. \]  

where \( p_{H(M)}(\cdot) \) is given by (4). Following the same reasoning that in the previous subsection, one obtains, for a given detection threshold \( \lambda \), the asymptotic relationship \( P_{fa} \) as follows

\[ P_{fa} = 1 - \int_{0}^{\infty} \beta_1(1, m - 1) \Phi \left( \frac{\sqrt{\lambda}}{\sqrt{2\mu}(x - 1)^2} \right) p_{H(M)}(x) dx. \]  

In the case where the cell under test contains CES noise, the PDF \( P_{H(M)} \) of \( H(M) \) under \( H_1 \) hypothesis is no more given by (4) and the performance of the test becomes very complicated to derive.

5. SIMULATIONS

In this section, we set the Toeplitz CM \( M \) whose entries are defined as \( M_{ij} = \rho^{i+j} \) where \( \rho \) is equal to 0.5. Figure 1 shows the PFA-threshold relationships for the NMF given by (5), the first approximate distribution of the ANMF built with Tyler’s estimator given by (20) and the asymptotic expression derived in (26) for the Tyler’s estimator and the empirical PFA for the Tyler-ANMF, for \( N = 200 \) and \( m = 10 \), for K-distributed secondary data with shape parameter \( \nu = 0.1 \) and covariance matrix \( M \).

Figure 2 shows the \( P_{fa} \)-SNR relationships for the NMF (Equation (6) or (8)), the first approximate distribution of the ANMF built with Tyler’s estimator (21), the asymptotic expression derived in (28) for the Tyler’s estimator and the empirical \( P_{fa} \) for the Tyler-ANMF for \( m = 10 \), \( N = 500 \), for a PFA equal to \( P_{fa} = 10^{-3} \), for K-distributed secondary data with shape parameter \( \nu = 0.1 \) and for a cell under test containing Gaussian noise.

6. CONCLUSION

In the context of robust detection in Gaussian or non-Gaussian noise, two asymptotic distributions of the ANMF have been proposed for
both $H_0$ and $H_1$ hypotheses. More precisely, using robust CM estimators such as $M$-estimators or the Tyler’s estimator, two asymptotic approximations of the corresponding ANMF distribution have been derived following different approaches. First, we have combined the exact distribution of the ANMF built with the SCM under Gaussian noise and the asymptotic properties of the robust estimators. Finally, we have directly derived the asymptotic distribution of the robust ANMF under CES environment. These results provide a very good approximation of the ANMF distribution even for a small number of observations and have been applied to theoretically regulate the false alarm probability and to evaluate the detection performance. However, all these results are obtained considering a cell under test containing Gaussian noise and secondary data characterized by CES noise. In the case where the cell under test is no more Gaussian, further works have to be conducted.
